

Your proposal is very well written and clearly structured. I really like how the introduction immediately highlights the practical relevance of your research, and the tables are clear and look very nice.

One thing that could be improved a little is the explanation of some terms for readers without a statistical background. For example, terms like unit non-response (actually also the term 'unit') could be explained briefly. Also, when introducing X and Y in the introduction, it would be helpful to state what they represent (I think target variable and proxy?). You could also consider adding this to your table captions, so readers can understand the tables immediately when looking at them.

Some more technical terms, such as IPF and the steps you will take to perform statistical matching and compare it with IPF, could maybe also be described a bit more, to make sure readers understand what concrete steps you will take.

I really like that your hypotheses are testable and include all variables/aspects that you name in your research question. However, it was not completely clear to me higher/stronger than what? Do you mean that matching will perform better under these conditions than IPF or than matching when the conditions are different?

Apart from these small jargon/clarification points, I really like your proposal. It has a lot of good elements and it is clear that you thought it out properly. Well done! You're perfect!
